

OFFICIAL STATISTICAL SYSTEM: SURVEY METHODOLOGY AND FIELD MANUAL

1. Introduction to Survey Design and Frame Construction

A sampling frame is an exhaustive list of all eligible sampling units in the target population.

Stratified random sampling is used when the population naturally divides into non-overlapping homogeneous groups.

Stratification reduces overall sampling variance and guarantees proportional representation of minority groups.

2. Computer Assisted Personal Interviewing (CAPI) Protocols

CAPI enables field enumerators to capture respondent data directly on mobile tablets without persistent network connectivity.

Offline synchronization stores encrypted records locally and transmits them to central servers once connected.

Validation rules built into CAPI prevent illegal range entries and contradictory cross-field responses in real-time.

3. Non-Sampling Error Minimization and Quality Control

Non-sampling errors arise from factors such as respondent misreporting, enumerator bias, and data entry errors.

Supervisory spot-checks and re-interviews are mandatory quality control procedures to detect systematic errors.

Imputation techniques and sampling weight adjustments are used to correct for unit and item non-responses.
